Windmill comDebug is a comprehensive and reliable piece of software designed to provide you with the ability of reading and controlling up to ten individual serial devices that you have connected to your computer. Following a quick and easy installation process, you can launch the

application and begin adjusting the 'COM Port Settings', ('Baud Rate', 'Data Bits', 'Parity', 'Stop Bits', 'Flow Control'), subsequently accessing the object that is connected to the input COM port. The main window of Windmill comDebug features several components, such as a 'Status' checking tool or a 'Reply Parser'

utility. The former will display the 'COM Input Lines' and the 'COM Output Lines', along with the 'Communications status', indicating their state as either 'True' (green color), or 'False' (red color). The latter is able to gather information from the messages of the device. You can 'Insert Steps' or 'Add Actions' to locate the source of

the data, while the 'Extract' menu enables you to obtain further information ('N Bytes', 'Float', 'Signed Byte', 'Integer LSB-MSB', and more) by allotting each item a channel. Windmill comDebug allows you to send 'Prompt' signals to the serial device and view the 'Reply' you receive, meaning the response it sends to your PC; on

rare occasions, an 'Acknowledgment' of the 'Reply' will be required by the instrument. The tool can prove handy even in testing your communication configurations, simply viewing the replies without saving them. This advanced program can assist you in identifying what is the cause of a particular problem in

your network and which are the devices that give you trouble, so you can attempt fixing the issue. To conclude, Windmill comDebug is an effective and user-friendly application that can be used to perform network debugging operations, by creating interactive communications between the connected devices

and your computer.

generally to the field of medical implant systems, and more particularly to a multipurpose ablation tool for use with stereotactic radiosurgery systems.

Background

Stereotactic radiosurgery (SRS) is a procedure used to treat patients with relatively small tumors. In this procedure, a

radiosurgical beam is focused to a very narrow target with a highly precise radiation isocenter, which is the centroid or center point of the beam, and which directs and focuses the radiotherapy beam. In prior art systems, a body part (e.g., a brain tumor) is imaged by a stereotactic radiosurgery system

and a proposed target point is selected. The treatment then begins with the direct delivery of a high dose of radiation to the target point. The procedure may be repeated with more radiation until the tumor is cured. For example, prior art radiosurgery systems are described in U.S. Pat. No. 6,699,273, the disclosure of

which is incorporated herein by reference. Some prior art stereotactic radiosurgery systems are capable of delivering a beam having a high dose of radiation to a small target without targeting the beam to a particular body organ or tissue. For example, such systems may be used to treat tumors in or

adjacent to the brain (i.e., intracranial tumors), the eye (i.e., choroidal melanomas), bone (i.e., metastatic bone lesions), liver, lung, spine, pancreas, kidney, and the adrenal gland. The radiation dose may be b7e8fdf5c8
